

ComparativeMarkerSelection Documentation

Module name: ComparativeMarkerSelection

Description: Computes significance values for features using several metrics,

including FDR(BH), Q Value, FWER, Feature-Specific P-Value,

and Bonferroni.

Authors: Joshua Gould, Gad Getz, Stefano Monti, Alper Uzun (Broad

Institute) gp-help@broad.mit.edu

The ComparativeMarkerSelection module includes several approaches to determine the features that are most closely correlated with a class template and the significance of that correlation. The module outputs a file containing the following columns:

- Rank The rank of the feature within the dataset based on the value of the test statistic.
 If a two-sided p-value is computed, the rank is with respect to the absolute value of the statistic.
- 2. **Feature** The feature name.
- 3. **Description** The description of the feature.
- 4. **Score** The value of the test statistic.
- 5. *Feature P* The feature-specific p-value based on permutation testing.
- 6. *Feature P Low* The estimated lower bound for the feature p-value.
- 7. **Feature P High** The estimated upper bound for the feature p-value.
- FDR (BH) An estimate of the false discovery rate by the Benjamini and Hochberg procedure (1). The FDR is the expected proportion of erroneous rejections among all rejections.
- 9. **Q Value** An estimate of the FDR using the procedure developed by Storey and Tibshirani (6).
- 10. **Bonferroni** The value of the Bonferroni correction applied to the feature specific p-value.
- 11. **maxT** The adjusted *p*-values for the maxT multiple testing procedure described in Westfall (7), which provides strong control of the FWER.
- 12. **FWER** (Family Wise Error Rate) The probability of at least one null hypothesis/feature having a score better than or equal to the observed one. This measure is not feature-specific.
- 13. **Fold Change** The class zero mean divided by the class one mean.
- 14. Class Zero Mean The class zero mean.
- 15. Class Zero Standard Deviation The class zero standard deviation.
- 16. Class One Mean The class one mean.
- 17. Class One Standard Deviation The class one standard deviation.
- 18. **k** If performing a two-sided test or a one-sided test for markers of class zero, the number of permuted scores greater than or equal to the observed score. If testing for markers of class one, then the number of permuted scores less than or equal to the observed score.

The results from the ComparativeMarkerSelection algorithm can be viewed with the ComparativeMarkerSelectionViewer.

Parameters:

Name	Description		
input filename	The input fileres, .gct		
cls filename	The class filecls		
confound variable cls	The class file containing the confounding variablecls		
filename	If you specify a confounding variable class file, permutations shuffle		
	the phenotype labels only within the subsets defined by that class		
	file. For example, in Lu, Getz, et. al. (2005), to select features that		
	best distinguish tumors from normal samples on all tissue types,		
	tissue type is treated as the confounding variable. In this case, the		
	confounding variable class file lists each tissue type as a phenotype		
	and associates each sample with its tissue type. Consequently,		
	when ComparativeMarkerSelection performs permutations, it		
		labels only among samples with the same	
	tissue type.		
test direction	The test to perform (up-regulated for class 0, up-regulated for class		
	, ,	1, two-sided). By default, ComparativeMarkerSelection performs the	
	two-sided test.		
test statistic	The statistic to use:		
	t-test	$\mu_A - \mu_B$	
		$\int \sigma_{A}^{2} + \sigma_{B}^{2}$	
		1 1/	
		V na nb	
		where	
		μ is the average	
		σ is the standard deviation	
	t-test (median)	n is the number of samples same as t-test, but uses median	
	i-lest (illediali)	rather than average	
	t-test (min std)	same as t-test, but enforces a	
	l test (min sta)	minimum value for σ (minimal	
		standard deviation)	
	t-test (median, min std)	same as t-test, but uses median	
		rather than average and enforces a	
		minimum value for σ (minimal	
		standard deviation)	
	SNR	μа – μв	
	(signal-to-noise ratio)		
		σ _A + σ _B where	
		μ is the average	
		σ is the standard deviation	
	SNR (median)	same as SNR, but uses median	
		rather than average	
	SNR (min std)	same as SNR, but enforces a	
		minimum value for σ (minimal	
		standard deviation)	
	SNR (median, min std)	same as SNR, but uses median	
	II CIVIT (ITICUIAII, ITIIII SIU)	Same as Civix, but ases illegial	

min std	Paired t-test Used only if test statistic i	rather than average and enforces a minimum value for σ (minimal standard deviation) computes a paired, 2-sample t- statistic ncludes the min std option. If σ is less than	
	min std, σ is set to min std.		
number of permutations	The number of permutations to perform (use 0 to calculate asymptotic p-values). The number of permutations you specify depends on the number of hypotheses being tested and the significance level that you want to achieve (3). The greater the number of permutations, the more accurate the p value.		
complete	Whether to perform all possible permutations. By default, <i>complete</i> is set to no and <i>number of permutations</i> determines the number of permutations performed. If you have a small number of samples, you might want to perform all possible permutations.		
balanced	Whether to perform balanced permutations.		
random seed	The seed for the random number generator.		
smooth p values	Whether to smooth p-values by using the Laplace's Rule of Succession. By default, <i>smooth p values</i> is set to yes, which means p-values are always less than 1.0 and greater than 0.0.		
phenotype test	Tests to perform when cls file has more than two classes: one-versus-all, all pairs. Note: The p-values obtained from the one-versus-all comparison are not fully corrected for multiple hypothesis testing.		
output file	The name of the output file		

Output Files:

An odf file of type ComparativeMarkerSelection
